

IPT10 Laboratory Activity 2

Introduction

At the end of this session, you should be able to:

- Form request handling using PHP
- Form input validation, and page redirection
- Understand and write PHP programs that manages Sessions
- Understand and write PHP programs that manages files

Answering and Submission Information

- Make a copy of this Google Document and encode your answers on your copy of this document
- Set the visibility or privacy of your document to be accessible to your laboratory facilitator/instructor. Share the document with this email natividad.romack@auf.edu.ph so the facilitator should be able to access and mark grades for your efforts in this activity.
- Carefully read each task, and action each items that are required
- Change the option from “Not Started” to “In Progress” to “Completed” depending on its actual state, for your personal tracking and facilitator notice.

Programming PHP Session

Use this codebase as a reference: <https://github.com/aufipt/labs-2627>

FIRST hit the FORK button, Clone your forked version of the code repository using git command, write the git command you've used to clone the repository

From your command prompt, open the lab2a by running

```
cd lab2a/
```

Run a built-in PHP server on that folder (Reference :

<https://www.php.net/manual/en/features.commandline.webserver.php>)

Discuss what is the difference of running your PHP programs using the built-in web server PHP and running the PHP program in an actual Web Server like Apache or Nginx

Using the **lab2a/** code, change the order and arrangement of the HTML inputs, and make sure it still works as expected, with additional things to do:

- Protect the registrant's password using any PHP's built-in hashing functions (try all, but just choose one)

References:

- md5 <https://www.php.net/manual/en/function.md5.php>
- sha1 <https://www.php.net/manual/en/function.sha1.php>
- password_hash
<https://www.php.net/manual/en/function.password-hash.php>
- Convert the date format to similar to this "June 15, 2001"
Reference: <https://www.php.net/manual/en/function.date.php>
- At the thank you page, display the age of the registrant, compute the age based on the entered birthdate
- Add validation for each step, ALL input fields are required, redirect back to the previous step if ANY of the form input is empty.

Step 1:

- Complete Name
- Birthday
- Contact Number
- Sex

Step 2:

- Program
- Complete Address

Step 3:

- Email Address
- Password
- Is Agree

Put your code repository of your updated arrangement of the registration form below.

File Programming (Displaying 10K Customers)

Use this codebase as a reference: <https://github.com/aufipt/labs-2425>

Use this dataset (10,000 customers in CSV)

<https://drive.google.com/uc?id=1N1xoxgcw2K3d-49tlchXAWw4wuxLj7EV&export=download>

Using the **lab2b/** code, modify the code to use and load the 10,000 customers, and modify your code to be able to handle displaying the 10,000 customers.

In Example #1 from this `microtime()` PHP function documentation

(<https://www.php.net/microtime>), you should be able to compute the time elapsed consumed executing the PHP program that displays all 10K customers

How much time does your program require to display all the 10,000 customers' data? Also, use a clock/timer on how much it is consumed to completely load the entire page. Do you think this is an ideal way to display data that is relatively large, explain your answer why?

File Programming (Writing data to a file)

Use this codebase as a reference: <https://github.com/aufipt/labs-2627>

If you would refer to the **lab2a/** and **lab2b/** code, we will combine its concepts and ability, by saving the registration data into a CSV file, and be able to display it and filter it.

- Using your text editor, create an empty file named **registrations.csv**
- After the user completed entering registration information, at the thank you page, the PHP program should insert or append the data into the CSV file. Use a PHP built-in function that writes to files, checkout these two functions and just choose one function for your program.

Options:

- fputcsv() <https://www.php.net/manual/en/function.fputcsv.php>
- fwrite() <https://www.php.net/manual/en/function.fwrite.php>
- Create another PHP file named **registrants.php** that would display all of the contents of the **registrations.csv** file into an HTML table.

Display the following data:

- Complete Name
- Birthday
- Age
- Contact Number
- Sex
- Program
- Complete Address
- Email Address

*Were you able to accomplish these two (2) tasks? What made you decide to choose one function over the other to write data into the **registrations.csv** file? Also, take a screenshot, paste the output of your HTML table of registrants data in this box. And lastly, paste the URL of your code repository.*
